Gentlemen,

I have gone through my inputs for VH for the modeling I did for circulating prior to cementing casing. I have tried several different inputs, and the closest I can get is 480 psi and that is taking out the fann 70 data which is not giving a reasonable estimate of true pressure. I have had several individuals double check and critiques my inputs and still cannot explain the difference. Looking at predictions from past modeling the pressure is never quite the same when we are drilling so I would not expect them to be the same for this model. Pressure is one of the hardest numbers to correlate. I would be interested to see what Landmark would predict as circulating pressures. I am open to sit down and discuss the inputs with the team. John and I went through some scenario's this morning and we could not do any better than 480 psi.

Regards,
