David - I have spoken with Bob Merrill and have more context now around the question being asked. I will do some work using the better quality Na Kika area compressibility data that we have and will revise the predictions of compressibility. The initial response was more to do with what we measured on the Macondo RSWCs, which as you correctly point out have some inherent biases.

I should have something later today on this.
Steve

Hi Kelly,

Not honoring sidewall data is the point isn't it? Because, we know from Santa Cruz data and intuitively that sidewall core data is conservative just from the way the grains are aligned. I don't get what you and Steve are driving at, we shouldn't be strictly confined to the sidewall data at Macondo or anywhere.

Sincerely,

David W. Schott

FYI... I don't know if we will increase it. Steve and Bob are going to talk. I'm still chasing aquifer size.

<< File: Macondo and Santa Cruz Formation Compressibility Calculator.ZIP >>

Hi Kelly - I don't think you can go much above 6 microsips and still honor the data. Here's a calculator that is consistent for both Macondo and Santa Cruz for the M56L. It is not wholly intuitive, but I can get with you and Bob to go over it at some point if you wish.

I'm busy now until about 3.45, but I could stop to see Bob afterwards to give him a heads up on its uscage if you wish.

Steve
